ECS 150 - System Calls

Prof. Joël Porquet-Lupine

UC Davis - FQ22

C program example

```
#include <fcntl h>
#include <stdio.h>
int main(int argc, char *argv[])
    int fd;
    char buf[4];
    if (argc < 2)
        exit(EXIT FAILURE);
    memset(buf, 0, sizeof(buf));
    fd = open(argv[1], 0 RDONLY);
    if (fd < 0) {
        perror("open");
        exit(EXIT FAILURE);
    read(fd, buf, sizeof(buf));
    close(fd);
    printf("Executable detection... ");
    if (buf[0] == 0x7F && buf[1] == 0x45
        && buf[2] == 0x4C && buf[3] == 0x46)
        printf("ELF");
    else if (buf[0] == '#' && buf[1] == '!')
        printf("script");
    else
        printf("Not an executable!");
    printf("\n");
    return 0;
                                             exec detector.c
```

Execution

```
$ make exec detector
cc -o exec detector exec detector.c
$ ./exec detector
$ ./exec detector /path/to/nofile
open: No such file or directory
$ ./exec detector exec detector
Executable detection... ELF
$ ./exec detector exec detector.c
Executable detection... Not an executable!
$ ./exec detector /bin/firefox
Executable detection... script
$ cat /bin/firefox
#!/hin/sh
exec /usr/lib/firefox/firefox "$@"
$ ./exec detector /usr/lib/firefox/firefox
```

Executable detection... ELF

Library functions

```
#include <fcntl.h>
#include <stdio.h>
...
    memset(buf, 0, sizeof(buf));
...
    fd = open(argv[1], 0_RDONLY);
    if (fd < 0) {
        perror("open");
        exit(EXIT_FAILURE);
    }
    read(fd, buf, sizeof(buf));
    close(fd);
...
    printf("Executable detection... ");
...
    printf("\n");
    exec detector...</pre>
```

Declaration

- Access via inclusion of headers
 - Function prototypes
 - Global variables (e.g. errno)
 - Type definitions (e.g. size_t)
 - Macros (e.g., 0_RDONLY)

Definition

- Actual code via library
- Linked at compile-time
- Dynamically loaded at runtime

Categories of libc functions

- 1. No privileged operation to perform
- 2. Always needs to request privileged operation from OS
 - Known as system call, or syscall
- 3. Sometimes needs to request privileged operation from OS

1. Regular functions

Usage example

```
char buf[4];
...
memset(buf, 0, sizeof(buf));
exec_detector.come
```

- memset() only needs to have access to array buf
 - buf is already part of the memory (defined in stack)
 - No need for special operations

Implementation example

Generic C implementation

```
void *memset(void *s, int c, size_t count)
{
    char *xs = s;
    while (count--)
        *xs++ = c;
    return s;
}
```

2. (Always) privileged functions

Usage example

```
fd = open(argv[1], O_RDONLY);
...
read(fd, buf, sizeof(buf));
close(fd);
exec_detector.c
```

- Need for special privileges: e.g.,
 - Verify that file exists on a physical medium accessible by computer (e.g., hard-drive, SD card, network, etc.)
 - Check that current user has permission to open it with specified mode
 - Actually read file's data from physical medium
- Sensitive operations passed to OS
 - Accessible via syscalls

Implementation example

• Specific to Linux

Specific to x86_64 processors

3. (Sometimes) privileged functions Usage example

```
printf("Executable detection...");
...
printf("\n");
exec_detector.c
```

- printf() prints to stdout which is internally buffered
 - Flushed when buffer is full, or when encountering \n
- Flushing requires to OS to actually write the characters
 - Use of (syscall) function write()

Printf vs write

```
printf("Hello ");
sleep(2);
printf("world!\n");

write(STDOUT_FILENO, "Hello ", 6);
sleep(2);
write(STDOUT_FILENO, "world!\n ", 7);
printf_write.c
```

System calls

Definition

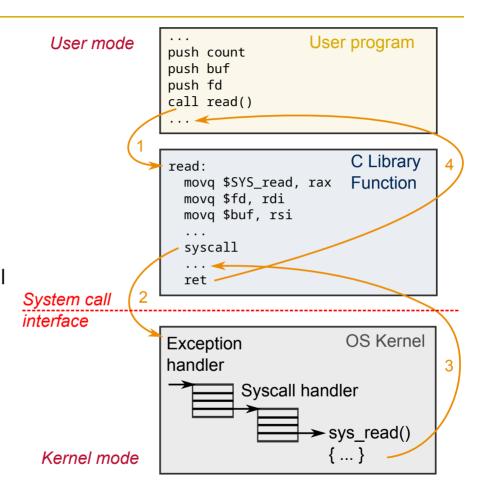

- Specific CPU instruction
- Immediate transfer of control to kernel code

Purpose

 Secure API between user applications and OS kernel

Main categories

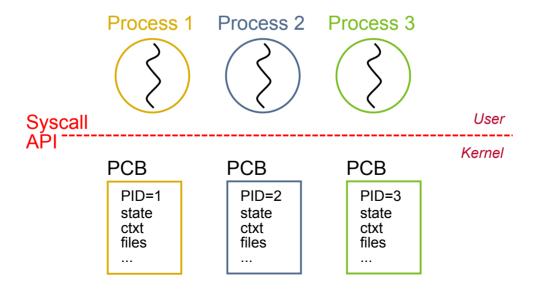

- Process management
- Files and directories
- Pipes
- Signals
- Memory management

Definition of a process

A process is a program in execution

- Each process is identified by its Process ID (PID)
- Each process runs its own memory space
- Each process is represented in the OS by a Process Control Block (PCB)
 - Data structure storing information about process
 - o PID, state, CPU register copies for context switching, open files, etc.

Main related functions/syscalls

- Process creation and execution
 - fork(): Create a new (clone) process
 - exec(): Change executed program within running process
- Process termination
 - exit(): End running process
 - wait()/waitpid(): Wait for a child process and collect exit code
- Process identification
 - getpid(): Get process PID
 - getppid(): Get parent process PID

fork()

- Running process gets cloned into a *child* process
- Child gets an (almost) identical copy of *parent*
 - o Same open files, command line arguments, memory, stack, etc.
- Child "resumes" at the fork() as well

```
$ ./fork_101
Hello world!
My favorite number is 66.
My favorite number is 66.
```

Distinguishing between parent and child

- fork() returns a value
 - *PID of the child* to the parent
 - o zero to the child
 - -1 to the parent in case of error

```
$ ./fork_201
I'm the parent!
I'm here now, bye!
I'm the child!
I'm here now, bye!
```

- This exact output is not guaranteed
- Parent and child are independent processes
- Scheduling up to OS

Fork illustrated (1/3) Process 1 fork() User Kernel PID=1 state ctxt files **PCB**

Fork illustrated (2/3) Process 2 Process 1 fork() User Kernel PID=1 PID=2 state state ctxt ctxt files files **PCB PCB**

Fork illustrated (3/3) Process 1 Process 2 fork() User Kernel 3' PID=1 PID=2 state state ctxt ctxt files files **PCB PCB**

ECS 150 - System Calls

Prof. Joël Porquet-Lupine

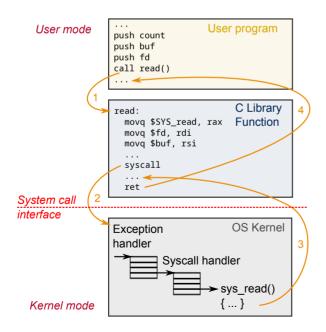

UC Davis - FQ22

Recap

C standard library

- Non-privileged functions
 - o E.g., memset()
- Always/sometimes privileged functions
 - o E.g., read()/printf()
 - Require system call

Syscall categories

- Process management
 - A process is a program in execution
 - PCB data structure
- Files and directories
- Pipes
- Signals
- Memory management

fork()

pid_t fork(void);

- Clones parent process into child process
- Both return from fork call
- Return value distinguishes between parent and child

exec()

- Current *process* starts executing another *program*
- Family of functions, with slight variations
 - exec[lv]p?e?() (see man page for details)

```
int main(void)
{
    char *cmd = "/bin/echo";
    char *args[] = { cmd, "ECS150", NULL};
    int ret;
    printf("Hi!\n");
    ret = execv(cmd, args);
    printf("Execv returned %d\n", ret);
    return 0;
}
```

```
$ ./execv
Hi!
ECS150
```

- Call to exec() functions never returns if it succeeds!
- Otherwise returns -1 and continues if it fails

exit()

- Termination of the current process
- Ability to return an exit value

Example

• Exit at any time during execution

```
if (error)
  exit(1);
```

• Or return from main()

```
int main(void) {
    ...
    return 0;
}
```

• Libc transparently exits

```
exit(main(argc, argv));
```

Exit value usage

```
$ 1s /
...
$ echo $?
0
```

```
$ ls /nodir
ls: cannot access '/nodir': No such file
or directory
$ echo $?
```

```
$ if [[ ! $(ls /nodir >& /dev/null) ]]; then echo "Expected..."; fi
Expected...
```

wait()/waitpid()

- wait() makes parent wait for *any* of its children to exit
 - Parent is blocked from execution in the meantime
- waitpid() enables more advanced options, such as
 - Specify PID of child to wait for
 - Don't block even if no children has exited

```
$ ./wait
Will exit soon!
Child returned 42
```

- Output order guaranteed
- Scheduling constrained by blocking call

Putting it together: fork() + exec() + wait()

```
int main(void)
    pid t pid;
    char *cmd = "/bin/echo";
    char *args[] = { cmd, "ECS150", NULL};
    pid = fork();
    if (pid == 0) {
        /* Child */
        execv(cmd, args);
        perror("execv");
        exit(1);
    } else if (pid > 0) {
        /* Parent */
        int status;
        waitpid(pid, &status, 0);
        printf("Child returned %d\n",
               WEXITSTATUS(status));
    } else {
        perror("fork");
        exit(1);
    return 0;
                                     fork exec wait.c
```

```
$ ./fork_exec_wait
ECS150
Child returned 0
```

system()

 Somewhat equivalent to what function system() does internally

```
system("/bin/echo ECS150");
```

• But with a lot more control!

The shell

- A **shell** is a user interface to run commands in the terminal
- Typically makes heavy use of process-related functions

Naive pseudo-implementation

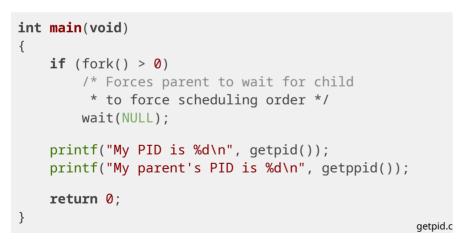

```
/* Repeat forever */
while (1) {
   char **command;
   display_prompt();
                                     /* Display prompt in terminal */
                                       /* Read input from terminal */
   read command(&command);
   if (!fork()) {
                                     /* Fork off child process */
       exec(command);
                                     /* Execute command */
                                     /* Coming back here is an error */
       perror("execv");
       exit(1);
   } else {
       /* Parent */
       waitpid(-1, &status, ♥); /* Wait for child to exit */
```

Extra features

Background jobs (&), redirections (< and >) for connecting stdin or stdout of the child to files (instead of the terminal), pipes (|) for connecting stdin or stdout of the child to other processes, and many more.

getpid()/getppid()

- Notion of a (family) tree of processes
 - Only one parent per process
 - But possibly multiple children
- In Unix, init (PID=1) is ultimate ancestor
 - Only process created from scratch by kernel (and not by forking)
- getpid() returns process' PID
- getppid() return its parent's PID

```
1
2
3
5 7 8
```

```
$ ./getpid
My PID is 406782
My parent's PID is 406781
My PID is 406781
My parent's PID is 162474
```

```
$ echo $$ 162474
```

System calls

Process management

Files and directories

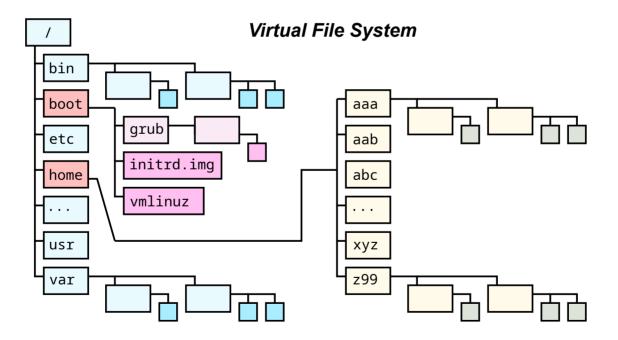

Pipes

Signals

Memory management

Concepts

- Files and directories in tree-like structure called **Virtual File System**
 - Internal nodes are directories, leaf nodes are files
- Every directory contains a list of filenames
- Every file contains an array of bytes

• VFS can aggregate files and directories from various physical media (local hard-drive, remote network share, etc.)

Main related functions/syscalls

- File interaction
 - open(): open (create) file and return file descriptor
 - close(): close file descriptor
 - read(): read from file
 - o write(): write to file
 - lseek(): move file offset
- File descriptor management
 - dup()/dup2(): duplicate file descriptor
- File characteristics
 - stat()/fstat(): get file status
- Directory traversal
 - getcwd(): get current working directory
 - chdir(): change directory
 - opendir(): open directory
 - closedir(): close directory
 - readdir(): read directory

Basic file interaction

- open() returns a **file descriptor** (FD), used for all interactions with file
 Closed by close() when done with file
- read()/write() operations are sequential, tracked by file offset
- lseek() can manipulate current file offset

```
#include <fcntl.h>
...
int main(void)
...
int fd;
...

fd = open("file_101.c", O_RDONLY);

read(fd, &c, 1);
printf("%c\n", c);
read(fd, &c, 1);
printf("%c\n", c);

lseek(fd, -2, SEEK_END);
read(fd, &c, 1);
printf("%c\n", c);

close(fd);
```

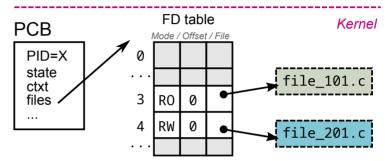

```
$ ./file_101
#
i
}
```

File descriptors

Definition

- Table of *open files* per process
 - Part of PCB
 - (Duplicated upon forking)
- FDs are simple indexes in the table

int fd1, fd2; fd1 = open("file_101.c", O_RDONLY); fd2 = open("file_201.c", O_RDWR);

Example

```
int fd1, fd2;

fd1 = open("file_101.c", O_RDONLY);
fd2 = open("file_201.c", O_RDWR);

printf("fd1 = %d\n", fd1);
printf("fd2 = %d\n", fd2);

file_201.c
```

```
$ ./file_201
fd1 = 3
fd2 = 4
...
```

Allocation

• open() always returns first available FD

```
close(fd1);
fd1 = open("file_201.c", O_WRONLY);
printf("fd1 = %d\n", fd1);
file 201.c
```

```
$ ./file_201
...
fd1 = 3
```

ECS 150 - System Calls

Prof. Joël Porquet-Lupine

UC Davis - FQ22

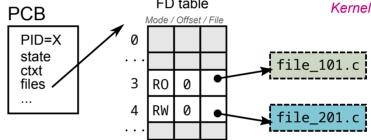

Recap

Process management

- fork()
 - Clone process
- exec()
 - Execute different program inside current process
- exit()
 - Terminate current process
 - Return exit value
- wait()
 - Parent for children processes to terminate
 - Collect exit value

Files and directories

File descriptors

Allocation

• open() always returns the *first* available FD

```
close(fd1);
  fd1 = open("file_201.c", O_WRONLY);
  printf("fd1 = %d\n", fd1);

$ ./file_201
...
fd1 = 3
```

Standard streams

Initially, three open file descriptors per process

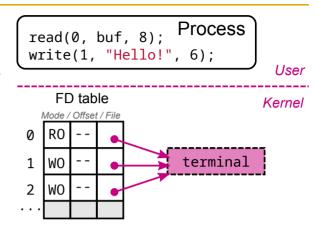

- 0: standard input (STDIN_FILENO)
- 1: standard output (STDOUT_FILENO)
- 2: standard error (STDERR_FILENO)

Example

```
write(STDOUT_FILENO, "Hello ", 6);
write(1, "Hello ", 6);
fprintf(stdout, "Hello ");
printf("Hello\n");

write(STDERR_FILENO, "World ", 6);
write(2, "World ", 6);
fprintf(stderr, "World\n");

standard_fds.c
```

```
$ ./standard_fds
Hello Hello Hello
World World World
```

Redirections

Can connect standard streams to other targets than the terminal

```
$ ./standard_fds > /dev/null
World World World
$ ./standard_fds 2> /dev/null | tr H J
Jello Jello Jello
```

```
$ ./standard_fds >& myfile.txt
$ cat myfile.txt
Hello Hello World World
Hello Hello
```

File descriptor manipulation

- dup2() replaces an open file descriptor with another
 - Avoid using deprecated dup()

```
int main(void)
    int fd;
    printf("Hello #1\n");
    fd = open("myfile.txt",
              O_WRONLY | O_CREAT,
              0644);
    dup2(fd, STDOUT FILENO);
    close(fd);
    printf("Hello #2\n");
    return 0;
                                      dup2.c
$ ./dup2
Hello #1
$ cat myfile.txt
Hello #2
```

```
Process
dup2(fd, STDOUT_FILENO);
                                        User
    FD table
                                      Kernel
  Mode / Offset / File
   R<sub>0</sub>
0
                         terminal
        0
1
   WO
2
   WO
                       myfile.txt
3
   WO
        0
```

File characteristics

- stat() returns information about a file, from a filename
- Same with fstat(), but from an FD

```
int main(int argc, char *argv[])
    struct stat sb;
    stat(argv[1], &sb);
    printf("File type:
                                ");
    switch (sb.st mode & S IFMT) {
        case S IFDIR: printf("directory\n");
                                                  break;
        case S IFREG: printf("regular file\n"); break;
                       printf("other\n");
        default:
                                                  break;
    printf("Mode:
                                %lo (octal)\n",
           (unsigned long) sb.st mode);
    printf("File size:
                                %lld bytes\n",
           (long long) sb.st_size);
    printf("Last file access: %s",
           ctime(&sb.st atime));
    return 0;
```

```
struct stat {
   dev t
             st dev;
                             /* ID of device containing file */
             st ino;
                             /* Inode number */
   ino t
                             /* File type and mode */
   mode t
             st mode;
                             /* Number of hard links */
   nlink t
             st nlink;
                             /* User ID of owner */
   uid t
             st uid;
   qid t
             st gid;
                             /* Group ID of owner */
                             /* Device ID (if special file) */
   dev t
             st rdev;
                             /* Total size, in bytes */
   off t
             st size;
   blksize t st blksize;
                             /* Preferred blocksize for I/O */
   blkcnt t st blocks;
                             /* Number of 512B blocks allocated */
   struct timespec st atim; /* Time of last access */
   struct timespec st mtim; /* Time of last modification */
   struct timespec st ctim; /* Time of last status change */
```

```
$ ./stat stat.c
                    regular file
File type:
                    100644 (octal)
Mode:
                    644 bytes
File size:
Last file access:
                    Fri Sep 18 16:32:02 2020
$ ./stat .
File type:
                    directory
                    40755 (octal)
Mode:
File size:
                    4096 bytes
Last file access:
                    Fri Sep 18 11:59:49 2020
```

Directory traversal

- getcwd()/chdir() to access the *current working directory*
- opendir()/closedir()/readdir() to access the entries of a directory

```
$ pwd
/home/iporquet
$ ./dir_scan /
Change CWD from '/home/iporquet' to '/'
Entry: ..
Entry: lib
Entry: home
Entry: etc
Entry: root
[...]
Entry: proc
Entry: tmp
Entry: dev
Entry: bin
Entry: sbin
Entry: mnt
Entry: .
Entry: usr
```

System calls

Process management

Files and directories

Pipes

Signals

Memory management

Pipe

Definition

- Inter-process communication (IPC)
- Pipeline of processes chained via their standard streams
 - stdout of one process connected to stdin of next process

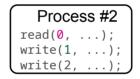

Example

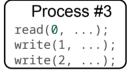

```
$ du -sh * | sort -h -r | head -3
1.2G ecs150
555M ecs36c
386M ecs30
```

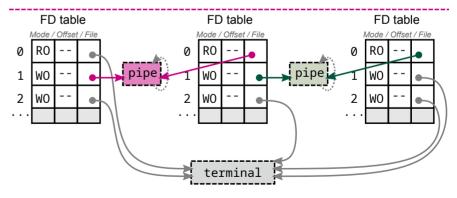

Details

- Internally implemented as anonymous files
 - Circular memory buffer of fixed size
 - Accessible via file descriptors and regular read/write transfers
- Processes run
 concurrently, implicitly
 synchronized by
 communication

```
Process #1
read(0, ...);
write(1, ...);
write(2, ...);
```

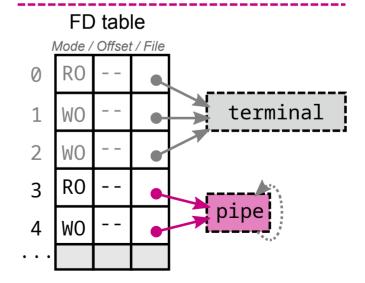

Pipe

pipe()

- Create a pipe and return two file descriptors via array
 - [0] for reading access, [1] for writing access

```
int main(void)
    int fd[2];
    char send[7] = "Hello!";
    char recv[7];
    pipe(fd);
    printf("fd[0] = %d\n", fd[0]);
    printf("fd[1] = %d\n", fd[1]);
    write(fd[1], send, 7);
    read(fd[0], recv, 7);
    puts(recv);
    return 0;
                                           pipe.c
$ ./pipe
fd[0] = 3
fd[1] = 4
Hello!
```

```
Process
int fd[2];
pipe(fd);
```

ECS 150 - System Calls

Prof. Joël Porquet-Lupine

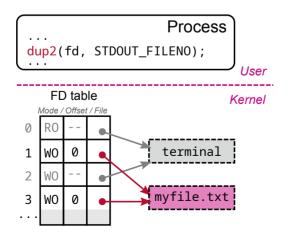

UC Davis - FQ22

Recap

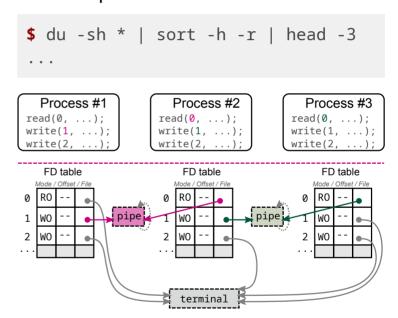

Files and directories

- Standard streams
 - 0 == STDIN_FILENO
 - 0 1 == STDOUT_FILENO
 - 0 2 == STDERR_FILENO
 - Connected to terminal by default when run from shell, unless redirected
- dup2()
 - Can redirect standard stream from within running process

Pipes

 Typically used to chain processes to one another and create complex commands

Pipe

Process pipeline example

Pseudo-code setting up command1 | command2

```
void pipeline(char *command1, char *command2)
   int fd[2];
   pipe(fd);
   if (fork() != 0) { /* Parent */
       /* No need for read access */
       close(fd[0]);
       /* Replace stdout with pipe */
       dup2(fd[1], STDOUT_FILENO);
       /* Close now unused FD */
       close(fd[1]);
       /* Parent becomes process1 */
       exec(command1);
   } else { /* Child */
       /* No need for write access */
       close(fd[1]);
       /* Replace stdin with pipe */
       dup(fd[0], STDIN_FILENO);
        /* Close now unused FD */
        close(fd[0]);
        /* Child becomes process2 */
       exec(command2);
```

System calls

Process management

Files and directories

Pipes

Signals

Memory management

Signals

Definition

- Form of inter-process communication (IPC)
- Software notification system
 - From process' own actions: e.g., SIGSEGV (Segmentation fault)
 - From external events: e.g., SIGINT (Ctrl-C)
- About 30 different signals (see man 7 signal)

Default action

In case process does not define specific signal handling

- Terminate process: e.g., SIGINT, SIGKILL*
- Terminate process and generate core dump: e.g., SIGSEGV
- Ignore signal: e.g., SIGCHLD
- Stop process: e.g., SIGSTOP*
- Continue process: e.g., SIGCONT

Handling or ignoring

- Possible to change default action (but not for all signals *!)
- Ignore signals
 - Mask of blocked signals
- Set signal handlers
 - Function to be run upon signal delivery

Signals

Main related functions/syscalls

- Sending signals
 - raise(): Send signal to self
 - kill(): Send signal to other process
 - alarm()/setitimer(): Set timer for self
 - Receive signal (SIGALRM/SIGVTALRM) when timer is up
- Blocking signals
 - sigprocmask(): Examine or change signal mask
 - sigpending(): Examine pending blocked signals
- Receiving signals
 - sigaction(): Map signal handler to signal
 - Also signal() but usage not recommended
 - pause(): Suspend self until signal is received

Signals

```
void alarm_handler(int signum)
   printf("\nBeep, beep, beep!\n");
int main(void)
    struct sigaction sa;
    sigset_t ss;
    /* Ignore Ctrl-C */
    sigemptyset(&ss);
    sigaddset(&ss, SIGINT);
    sigprocmask(SIG_BLOCK, &ss, NULL);
    /* Set up handler for alarm */
    sa.sa handler = alarm handler;
    sigemptyset(&sa.sa_mask);
    sa.sa flags = 0;
    sigaction(SIGALRM, &sa, NULL);
    /* Configure alarm */
    printf("Alarm in 5 seconds...\n");
   alarm(5);
    /* Wait until signal is received */
   pause();
    /* Bye, ungrateful world... */
   raise(SIGKILL);
   return 0;
                                                signal.c
```

System calls

Process management

Files and directories

Pipes

Signals

Memory management

Memory

Division of labor

User C library

- malloc()/free() for dynamic memory allocation
 - Heap memory segment (at the end of data segment)
- Fine-granularity management only
 - When heap is full, syscall to kernel to request for more

OS/Kernel

- Memory management at "page" level
- Allocation of big chunks (many pages) to user library

Related functions/syscalls sbrk()/brk()

- Linear increase of data segment
- Old way of allocating heap space ¹
- Legacy function now

mmap()

- Map pages of memory in process' address space
- Can also map a file's contents
- Extremely versatile and powerful function
